

couplings

Lamidisc® all steel coupling

Lamidisc® coupling

JAURE has been engaged more than 35 years in the development and production of couplings that are used in a variety of applications ranging from light to heavy duty and low speed to high speed.

From our commitment for continuous improvement JAURE has developed a new disc coupling that provides a reliable transmission of mechanical power from driving to driven machines.

Disc couplings provide compensation for axial, angular and radial¹ misalignment. In general they have the following advantages:

- No need for lubrication and maintenance.
- There is no need to disassemble the coupling to inspect. Additionally, the condition of the discs can be checked while the machine is running, using a strobe light.
- The machine misalignment can be assessed.
- Torsionally rigid without any backlash.
- No wearing parts, high resistance to harsh environmental conditions.
- Infinite life if properly aligned.

Nevertheless, disc pack couplings have only a few disadvantages:

- They tend to impose large axial forces on the thrust bearings if the machines are not properly spaced.
- The life of the discs is a function of the operating misalignment of the coupling.
- Piloting of the disc pack to the hubs is a key factor especially for high speed applications.

However, if misalignment is kept within specified limits, these couplings can last as long as the machines on which they are installed.

To improve on these disadvantages, various couplings manufacturers have modified the profile in many ways. JAURE has accomplished a superior disc profile by using the more recent Finite Element Analysis. As a result of our development work, the LAMIDISC® - 6 Bolts, can operate at 1.5° angular misalignment² continuously without losing any torque capability, or in other words: impose smaller forces on the bearings for a given misalignment and transmit more torque than other competitive couplings.

Disc finite analysis elements

The angular misalignment between shafts can vary from 0 to 2 times α as per the figure shown:

α = represents the angular misalignment per disc-pack

α (for Lamidisc®-6 under 202) = 1.5°
 α (for Lamidisc® above or equal 202) = 1°
 α (for Lamidisc®-8) = 0.5°
 α (for Lamidisc®-10) = 0.4°

- 1- For radial misalignment 2 disc packs must be used.
- 2- See graph in Page 5.

Lamidisc® coupling

JAURE uses fitted bolts to pilot their couplings but for high speed applications has also found a straight-forward method of piloting the disc packs to their hubs (see below). By machining rabbets in the washers that are used to unitize the disc pack, it ensures the repeatability of residual unbalance standards, as mandated by API 671.

Disc piloting (Jaure Patent)

The discs of the LAMIDISC® couplings are made of high - grade stainless steels (AISI-301), ensuring not only a high strength and high endurance to fatigue, but also the resistance to most environmental conditions. Furthermore, discs can be covered with a low friction coefficient coating to improve the resistance to fretting wear.

LAMIDISC® couplings utilizes unitized disc packs with 6, 8 and 10 bolts. The higher the number of bolts, the larger the torque that can be transmitted but the smaller the misalignment the couplings can accomodate.

The Lamidisc® couplings can also be fitted with overload bushings which also serve as an anti-flail device.

The design and manufacture of LAMIDISC® couplings is integrated into a certified Quality System according to DIN ISO 9001 to fulfil the high quality demands on LAMIDISC® couplings.

The LAMIDISC® couplings are offered in a variety of configurations to fit most applications: in addition, our engineering department can customize a coupling to special requirements: close - coupled, drop-out, electrically insulated, vertical mounting, safety couplings, etc. A notable design is our Lamidisc® CX (reduced moment) coupling, that not only has the anti-flail device mandated by API 610, but offers a low weight and a short center of gravity to bearing distance.

Different disc profiles

Technical modifications reserved

Selection procedure

1.- Select the coupling type.

2.- Select the driven machine service factor SFA from Table 1.

Select the driving machine service factor SFD from Table 2.

Care should be taken when the driving machine is other than a standard electric motor or turbine. Some engines will impose extra fluctuations on the drive system and allowance should be made accordingly. Please refer to Table 2.

The two service factors SFA and SFD must be added resulting in the combined service factor SF .

Lamidisc® coupling

3.- Calculate the minimum torque rating as per,

$$\text{Torque (Nm)} = \frac{9550 \cdot \text{Nominal power (kW)} \cdot \text{SF}}{n \text{ (rpm)}}$$

4.- The coupling to be selected must have an equal or greater rated torque capacity than the torque calculated in 3. Check the peak or starting torque capacity of the selected coupling. For systems which frequently utilize the peak torque capability of the power source, verify that the magnitude of the peak torque does not exceed twice the rated nominal torque of the coupling selected.

5.- Check if existing or predicted axial, angular and offset misalignments are within permissible values as shown in the catalog. The permissible axial misalignment and torque depend on the angular misalignment as per shown below. (Angular misalignment is given for a disc pack. Axial misalignment is measured for a complete coupling with 2 disc packs).

The listed values represent the total permissible misalignment which may occur during operation. Consult the appropriate operating instructions for allowable shaft misalignments when installing the coupling.

Angular and radial misalignment

Axial misalignment

The permissible offset or radial misalignment is given by :

$$\Delta K_r = \tan \Delta K_w \cdot L, \text{ where } L \text{ is the distance between the discs.}$$

6.- Check the maximum hub bores, speed and if the shaft to hub assembly will transmit the torque. If the speed exceeds 3000 r.p.m. please contact our Technical Department.

7.- Check if balancing is needed following the dynamic balancing guide below. This graph relates the maximum speed unbalanced with the total weight of the coupling and it should be considered only as a guide. Tabulated speeds are based solely on the maximum stress considerations on the flange. For a through analysis please contact JAURE.

Technical modifications reserved

Example of selection

Select a spacer coupling to connect a standard electric motor to rated at 250 kW to, running at 1000 r.p.m, to a centrifugal pump rated at 230 kW. The shafts are $\varnothing 75$ mm and $\varnothing 70$ mm respectively.

1. Coupling type SX

2. Service factor

a) Centrifugal pump	1.0
b) Electric motor	0.0
TOTAL	1.0

3. Required minimum torque rating

$$\text{Torque} = \frac{9550 \times 230 \times 1}{1000} = 2197 \text{ Nm}$$

The coupling selected is SX size 185-6 with a nominal torque of 3300 Nm, peak torque of 6600 Nm, $\Delta K_a = \pm 3.7$ mm and $\Delta K_w = \pm 1.5$ °.

4. Check peak torque (Coupling peak torque is $3300 \times 2 = 6600$ Nm)

5. Check expected misalignment .

6. Check maximum bores: Lamidisc® 185-6 has a maximum bore diameter of 80 mm, therefore this dimension is larger than the existing shaft diameters. The speed check shows it to be less than allowable speed (1000 rpm < 6850 rpm).

How to specify a LAMIDISC® coupling

The following data have to be given JAURE in order to verify that a proper selection has been made.

Application and type of duty.

Type of prime mover , power and speed.

Shaft types and sizes , keyway dimensions , hub length.

Expected misalignments.

Type of driven equipment.

Coupling type , size and DBSE (Distance between shaft ends).

Space limitations.

Special requirements (vertical mounting , spark free , API 610 or 671 , etc).

Applications: some examples

Larger sizes are available on demand.

1) Operating speed must be equal or less than permissible speed. Permissible speeds could be limited by the weight and critical speeds of spacers. Check the dynamic balancing guide and critical speeds on page 5.

2) Max. rotation speeds considered in special mat. and/or execution. For higher rotation speeds, please consult JAURE.

3) The maximum bores shown are for cylindrical or taper shafts with keys. For other type of connections consult JAURE.

4) Dimension DBSE is the distance between shafts ends and is a variable parameter.

5) Value of complete coupling with DBSE min, d1 and d2 max., GD² = 4J.

6) The value for axial coupling is given for a complete 2 disc pack coupling. Angular misalignment is given per pack. Refer to page 5 for combined permissible misalignment.

7) The dimension F is required for dismounting the fitted bolts.

8) Overload bushings (CCR) are available on demand.

- Operating speed must be equal or less than permissible speed. Permissible speed could be limited by the weight and critical speeds of spacers. For higher speeds consult JAURE.
- The maximum bores shown are for cylindrical or taper shafts with keys. For other type of connections consult JAURE.
- Dimension DBSE is the distance between shafts ends and is a variable parameter. DBSE can be reduced, but in this case disc-packs can not be removed radially without moving one of the machines.
- Value of complete coupling with DBSE min., d1 and d2 max., $GD^2=4J$.
- The value for axial misalignment is given for a complete 2 disc pack. Angular misalignment is given per pack. Refer to page 5 of the catalogue for combined permissible misalignment.
- The dimension F is required for dismantling the fitted bolts.

Larger sizes are available on demand

- (1) For coupling selection, apply corresponding service factor (SF=2 minimum)
(2) Values for St-52.3 disc material balanced to G 6.3 ISO 1940. Consult JAURE for couplings operating at higher speeds.
(3) Max. admissible bore for couplings with DIN 6885/1 keys. For other types of keys or connections please consult JAURE.
(4) Ø995mm brake disc's thickness: 40mm.
(5) Dimension DBSE is the distance between shaft ends, and is a variable parameter.
(6) Tightening torques are given in dry condition. For lubricated bolts reduce these values by 20%.
(7) Value of complete coupling with std. DBSE, d1 and d2 max., GD² = 4J
(8) The value for axial misalignment is given for a complete 2 disc pack. Angular misalignment is given per pack. Refer to page 5 for combined permissible misalignment.

Larger sizes are available on demand.

1) Nominal Torque shrink disc connection included

2) Operating speed must be equal or less than permissible speed. For higher rotation speeds, please consult JAURE.

Permissible speeds could be limited by the weight and critical speeds of spacers. Check the dynamic balancing guide on page 5.

3) Shafts must be machined with tolerance g6. For other tolerances consult JAURE.

4) The minimum bore is given for Nominal Torque. Smaller bores are possible but transmitted torque is decreased. Consult JAURE.

5) Dimension DBSE is the distance between shafts ends and is a variable parameter.

6) Value of complete coupling and shrink discs with std. DBSE, d1 and d2 max., $GD^2=4J$.

7) The value for axial misalignment is given for a complete 2 disc pack. Angular misalignment is given per pack. Refer to page 5 for combined permissible misalignment.

Different sizes are available on demand.

1) All composite tubes made in CARBON FIBER. GLASS FIBER tubes available on demand.

2) Nominal Torque considered with stainless steel hardware

3) The maximum bores shown are for cylindrical or taper shafts with keys. For other type of connections consult JAURE.

4) The value for axial misalignment is given for a complete 2 disc pack. Angular misalignment is given per pack. Refer to page 5 of the catalogue for combined permissible misalignment.

5) The maximum DBSE and speed could be increased with a special design by means of a bigger tube diameter. Please consult JAURE.

NOTE: the fan speed and number of blades is required to select a composite drive shaft for a cooling tower application.

For cooling towers, min. service factor=2

Larger sizes are available on demand

1) The maximum bores shown are for cylindrical or taper shafts with keys. For other type of connections consult JAURE.

2) Value of complete coupling with DBSE min, d1 and d2 max., GD² =4J.

3) This configuration allows only stated axial and angular misalignments. RADIAL MISALIGNMENTS ARE NOT ADMISSIBLE.

4) Overload bushings (SUR) are available on demand.

Lamidisc® coupling

Applications

Herewith are shown various examples for the Lamidisc® coupling. Our Technical Department is ready to study the most suitable configuration to fit your requirements.

Lamidisc® coupling

Lamidisc® DOAE-345-8 CFRP: for patrol boats propulsion

Glass fiber shaft for Lamidisc® SXGF-228-6/3296 mm for cooling towers with bonded and bolted joint.

AISI 301 disc-pack with an antifretting and anti-rust coating.

Dynamic balancing.

Lamidisc® SXCF-255-6 with carbon fiber shaft.

Lamidisc® SX-730-10 & DO-675-8

Lamidisc® SXGF-302-6/752 mm with glass fiber shaft for windmills.

Superficial treatment for composite shaft

Bonded joint curing

Technical modifications reserved

Lamidisc® coupling

Conical sleeve for hydraulic dismounting

Lamidisc® DO-570-8.

Lamidisc® DOAE-475-8 - CFRP: for fast ferry shaft lines

Lamidisc® DO-675-8 SP for marine main propulsion (waterjet)
(11.640 kW @ 558 rpm)

Custom-made solutions, high speed and API (610, 671) couplings.

Detail of Lamidisc® DO-675-8 SP with electrical insulation.

Lamidisc® SXRFD-202-6 for cranes.

Installation of hubs . Machinery alignment . Installation of disc packs and spacer.

1.- Installation of the hubs on the machine shafts.

a) Straight shafts with keyway.

Jaure supplies Lamidisc® hubs machined with **H7** (ISO-286) tolerance. Jaure recommends that the shaft should be machined for an interference fit, using tolerance **s6** (ISO-286).

Whenever the shafts are already machined with a different tolerance from s6, Jaure will customize the hub bores. The following tolerances are recommended by JAURE.

Shaft tolerance	Hub tolerance
h6	S7
k6	M7
m6	K7
n6	J7
p6	H7

b) Clamping devices.

When clamping devices, such as tapered bushings, are used, JAURE recommends that the shafts should be machined with **g6** tolerances, for a standard Lamidisc® bore, (H7).

For other type of connections, please consult our Technical Department.

2.- Machinery Alignment.

As long as the machines are aligned within the mounting specifications from this catalog, the Lamidisc® couplings will operate for a long time. However, it should be understood that the useful life of any disc pack coupling is directly influenced by the operating misalignment: the better the alignment, the longer the coupling life.

Although the Lamidisc® couplings can operate satisfactorily at the misalignment listed in the catalog, both the coupling life and machine bearing wear can be greatly improved if the machines are aligned better than the maximum value that the coupling can accommodate. JAURE recommends that the working misalignment should not exceed 20 % of the catalog values. Therefore, the following formulas show JAURE's recommendations for maximum misalignment.

Three types of machine misalignment (offset, angular, and axial) should be checked. JAURE has the following recommendations:

• **The maximum radial misalignment** that the Lamidisc® coupling can accommodate is a function of the distance between the disc packs. For the configurations SX this distance is practically the same as the distance between the shaft ends. This statement is not valid for other configurations, such as CC, DO, CX, DX.

If shafts have an offset misalignment with minimum angular misalignment, the following maximum values for the offset are applicable.

Lamidisc® with 6 bolts	$TIR < (\text{disc pack to disc pack distance}) / 150$
Lamidisc® with 8 bolts	$TIR < (\text{disc pack to disc pack distance}) / 300$
Lamidisc® with 10 bolts	$TIR < (\text{disc pack to disc pack distance}) / 350$

(NOTE : TIR is the Total Indicator Reading, which is twice the shaft offset)

• **The maximum angular misalignment** at each disc pack is listed in the tables. This angular misalignment can be verified by measuring the flange-to-flange distance (see figure below) and subtracting the smallest reading from the largest reading (Y-Z). The maximum value of (Y-Z) depends on the flange diameter, therefore on the coupling size. Based on the data from the tables, the following maximum values for (Y-Z) are recommended:

Lamidisc® with 6 bolts	$(Y-Z) \leq \text{Coupling size} / 300$
Lamidisc® with 8 bolts	$(Y-Z) \leq \text{Coupling size} / 600$
Lamidisc® with 10 bolts	$(Y-Z) \leq \text{Coupling size} / 700$

Example: For Lamidisc® size 380-6 (maximum angular misalignment of 1 °), (Y-Z) should not exceed $380/300 = 1.27$ mm.

• **The axial misalignment** allowable between shafts during installation, should not exceed 20% of the allowable displacement given in the catalog. This displacement is a function of the coupling size and the number of bolts utilized. The larger the size the larger axial displacement.

The axial displacement creates large stresses in the discs. For a long life it is recommended that the discs are as close as possible to being flat. Therefore, the movements of the shafts as caused by thermal expansion should be carefully considered. For instance, if the distance between shaft ends changes by -5 mm (the shafts are coming closer to each other) from cold to hot machines, the distance between shaft ends with cold machines should be intentionally be made larger by 5 mm when the coupling is installed.

3.- Installation of disc packs and spacer.

The installation of the coupling components depends of the type Lamidisc® coupling: the only tool needed are regular wrenches or sockets, and a torque wrench. **Tightening the bolts of a coupling according to specification is very important.**

Lamidisc® coupling

Values for Disc-pack bolts tightening torque.

Size	Disc bolt non-lubricated tightening torque (Nm)	Size	Disc bolt non-lubricated tightening torque (Nm)	Size	Disc bolt non-lubricated tightening torque (Nm)	Size	Disc bolt non-lubricated tightening torque (Nm)
90	13	255	450	440	2000	675	9900
110	30	278	450	475	2600	700	12200
132	30	302	600	505	3300	730	12200
158	60	325	600	540	4100	760	14800
185	100	345	780	570	5100		
202	150	380	1100	605	6200		
228	230	410	1500	635	7900		

NOTA: For lubricated threads reduce the given values by 20 %.

For hardware (Bolts and nuts) in stainless steel mat., consult JAURE.

Values for spacer (type CX) and flange (type DX) bolt non-lubricated tightening torque in Nm.

Size	CX and DX types	Size	CX and DX types
132-6/10	8	302-8/40	230
158-6/15	20	325-8/45	230
185-6/20	68	345-8/50	325
202-6/25	108	380-8/55	325
255-6/30	108	410-8/60	325
278-8/35	230	540-8/70	565

Values of tightening torque in Nm for flange connecting bolts. Types DO-6 and DO-8.

Size	Bolt non-lubricated tightening torque (Nm)	Size	Bolt non-lubricated tightening torque (Nm)	Size	Bolt non-lubricated tightening torque (Nm)	Size	Bolt non-lubricated tightening torque (Nm)
90-6	15	278-6	580	505-6	2000	410-8	565
110-6	35	302-6	780	278-8	108	475-8	660
132-6	35	325-6	780	302-8	108	505-8	660
158-6	69	345-6	580	325-8	325	540-8	760
185-6	120	380-6	780	345-8	325	570-8	760
202-6	190	410-6	1000	380-8	325	605-8	760
228-6	295	440-6	1500				
255-6	580	475-6	2000				

NOTE: For lubricated threads reduce the given values by 20 %

For hardware (Bolts and nuts) in stainless steel mat., consult JAURE.

a) Standard configuration. SX and SXR types.

The only bolts to be installed and tightened are the ones that attach the disc packs to the hubs and spacer. Place the spacer and install the bolts with their heads at the flange and not at the disc pack. The nuts shall be turned with the torque wrench to the specified torque, while the heads of the bolts are held stationary.

b) Close coupled configuration. CC and CCR types.

The CC coupling type was created for use with machines that have the shafts too close for the use of the standard SX coupling. The outside diameter of the hubs was reduced to be inserted in the inside of the hole of the disc pack.

To install the hubs on their shafts, the shafts must be spaced apart at least the length of one hub (see dimension I1 and I2 in the table). To install the coupling, the disc packs can be first attached with their bolts to the spacer, and then slide over one of the hubs, and attached to it. Next, the machines must be brought in position so that the second disc pack can be attached to its hub.

The machine alignment can now be performed. Because the spacer covers the shaft ends, the axial spacing must be checked by measuring the flange to flange distance (dimension "S" in tables). The offset and angular misalignments can be checked as previously described.

The bolts that attach the disc packs to the hubs and spacer must be tighten to specification, using a torque wrench at the nuts, while the bolts heads are held stationary.

c) Drop-out configuration. DO type.

The drop-out configuration allows the installation and removal of the coupling assembly , without the need to remove the hubs from their shafts. The coupling is received from JAURE fully assembled, with the bolts tightened to specifications. If, however, there is a need to disassemble the coupling assembly (in case the disc packs need to be replaced) the nuts should be tightened to specification using a torque wrench, while the bolt heads are held stationary. Machine alignment should be done before the coupling assembly is in place.

The coupling assembly will not fit between the hubs, as long as the shaft-to-shaft distance was correctly set. The coupling ends should be brought together by compressing the disc packs using the shipping screws, so that the assembly will fit between the male rabbets.

Once in position, the coupling will snap in place, and the bolts that attach the assembly to the shaft hubs must be tightened to JAURE specifications using a torque wrench. This operation must be carefully performed, as these bolts transmit the full coupling torque.

To remove the coupling assembly first remove all the bolts that retain it to the hubs. Then compress the assembly by introducing the existing flange bolts in the shipping holes and press the coupling away from the male rabbets.

d) Reduced moment coupling with spacer according to AGMA 516, CX type.

The reduced moment configuration is used whenever the shaft stresses require that the center of gravity of the coupling is very close to the machine bearings. This configuration also allows either machine to be removed by dropping the spacer, without the need to disturb the disc-pack assemblies.

The installation of this coupling requires the following steps:

- Install the hubs on their shafts.
- Measure and adjust the shaft to shaft (DBSE) distance.
- Align the machine shafts as previously described.
- Attach one disc pack and a short sleeve at each hub, by tightening the nuts to specifications, while holding the bolt heads stationary.
- Place the spacer between the two sleeves. It should fit without interference, or without a gap remaining between the flanges. Correct the machine spacing if necessary, as any axial displacement can adversely affect coupling's long term performance.
- Insert the flange bolts and tighten the nuts to specifications using a torque wrench and adaptor, while holding the bolt heads stationary.
- Recheck the alignment, and correct if necessary.

e) Drop-out coupling with floating assembly, flanges according to AGMA 516, DX type.

Machine alignment should be done before the coupling assembly is in place. The drop-out configuration allows the installation and removal of the coupling assembly, without the need to remove the hubs from their shafts. The coupling is received from Jaure fully assembled, with the bolts tightened to specifications. If, however, there is a need to disassemble the coupling assembly (in case the disc packs need to be replaced) the nuts should be tightened to specification using a torque wrench, while the bolt heads are held stationary.

The coupling assembly will fit between the hubs, as long as the shaft-to-shaft distance was correctly set. Once in position, the nuts that attach the assembly to the shaft hubs must be tightened to specifications using a torque wrench and adaptor, while the bolt heads are held stationary. This operation must be carefully performed, as these bolts transmit the full coupling torque.

Technical modifications reserved

DO Type with STANDARD HUB

Mounting and dismantling instructions.

Mounting

- ① - Shipping position.
 - ② - Remove the flange bolts (and shipping bolts if shipping bushings are supplied).
 - ③ - Introduce flange bolts or shipping bolts in the shipping holes in order to compress the central element.
 - ④ - Bolt up with the recommended tightening torque.
 - ⑤ - Work position.
- IMPORTANT:** Remove shipping bushings before installation. (when supply, only with big couplings).

Dismounting

- ① - Work position.
- ② - Remove flange bolts.
- ③ - Introduce the flange bolts in the shipping holes in order to compress the central element.

DO Type with JUMBO HUB

Mounting and dismantling instructions.

Mounting

- ① - Shipping position.
 - ② - Remove the long and short flange bolts (if shipping bushings are supplied).
 - ③ - Introduce the shipping-dismounting bolts (short bolts) in the shipping holes in order to compress the central element.
 - ④ - Bolt up the long bolts with the recommended tightening torque.
 - ⑤ - Work position.
- IMPORTANT:** Remove shipping bushings before installation. (when supply, only with big couplings).
- After, remove shipping bolts and store in screw bores of the hubs.

Dismounting

- ① - Work position.
- ② - Remove flange bolts (long bolts) and shipping-dismounting bolts (short bolts).
- ③ - Introduce the shipping-dismounting bolts (short bolts) in the shipping holes in order to compress the central element.
